# MacDown

Hello there! I'm **MacDown**, the open source Markdown editor for OS X.

Let me introduce myself.

Markdown and I

Markdown is a plain text formatting syntax created by John Gruber, aiming to provide a easy-to-read and feasible markup. The original Markdown syntax specification can be found here.

MacDown is created as a simple-to-use editor for Markdown documents. I render your Markdown contents real-time into HTML, and display them in a preview panel.
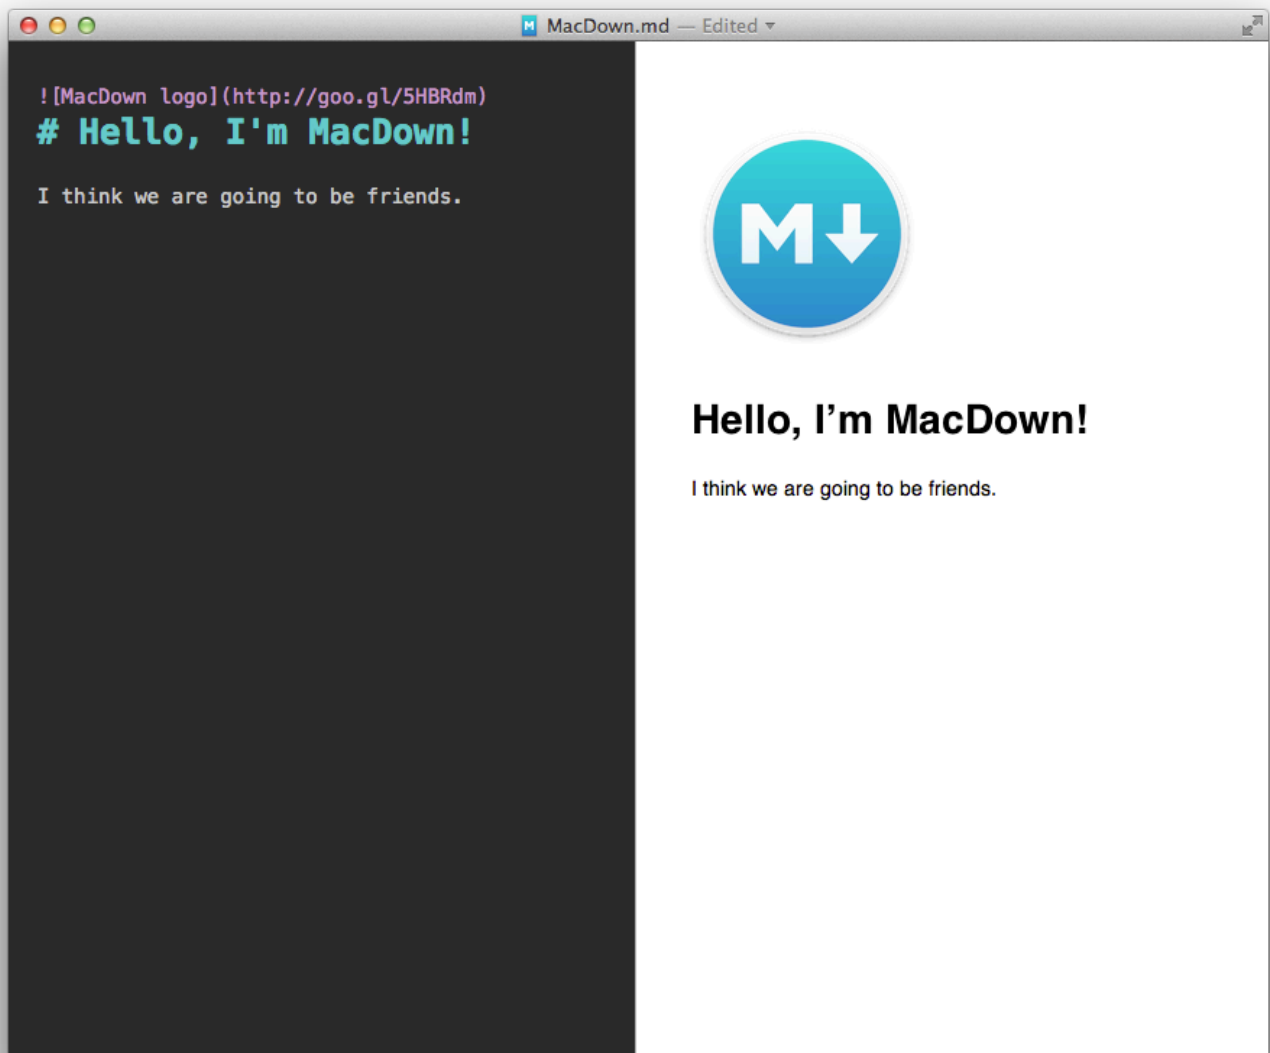

I support all the original Markdown syntaxes. But I can do so much more! Various popular but non-standard syntaxes can be turned on/off from the **Markdown** preference pane.

You can specify extra HTML rendering options through the **Rendering** preference pane.

You can customize the editor window to you liking in the **Editor** preferences pane:

You can configure various application (that's me!) behaviors in the **General** preference pane.

The Basics

Before I tell you about all the extra syntaxes and capabilities I have, I'll introduce you to the basics of standard markdown. If you already know markdown, and want to jump straight to learning about the fancier things I can do, I suggest you skip to the **Markdown** preference pane. Lets jump right in.

Line Breaks

To force a line break, put two spaces and a newline (return) at the end of the line.

```
These lines
won't break

These lines
will break
```

Strong and Emphasize

Strong: `**Strong**` or `__Strong__` (Command-B)
Emphasize: `*Emphasize*` or `_Emphasize_` [1] (Command-I)

Headers (like this one!)

```
Header 1
========

Header 2
--------
```

or

```
# Header 1
## Header 2
### Header 3
#### Header 4
##### Header 5
###### Header 6
```

Links and Email

Inline

Just put angle brackets around an email and it becomes clickable: uranusjr@gmail.com
`<uranusjr@gmail.com>`

Same thing with urls: http://macdown.uranusjr.com
`<http://macdown.uranusjr.com>`

Perhaps you want to some link text like this: Macdown Website
`[Macdown Website](http://macdown.uranusjr.com "Title")` (The title is optional)

Reference style

Sometimes it looks too messy to include big long urls inline, or you want to keep all your urls together.

Make [a link](#) `[a link][arbitrary_id]` then on it's own line anywhere else in the file:
`[arbitrary_id]: http://macdown.uranusjr.com "Title"`

If the link text itself would make a good id, you can link [like this](#) `[like this][]` , then on it's own line anywhere else in the file:
`[like this]: http://macdown.uranusjr.com`

Images

Inline

`![Alt Image Text](path/or/url/to.jpg "Optional Title")`

Reference style

`![Alt Image Text][image-id]`
on it's own line elsewhere:
`[image-id]: path/or/url/to.jpg "Optional Title"`

Lists

- Lists must be preceded by a blank line (or block element)
- Unordered lists start each item with a `*`
- `-` works too

    - Indent a level to make a nested list
        1. Ordered lists are supported.
        2. Start each item (number-period-space) like `1.`
        3. It doesn't matter what number you use, I will render them sequentially
        4. So you might want to start each line with `1.` and let me sort it out

Here is the code:

```
* Lists must be preceded by a blank line (or block element)
* Unordered lists start each item with a `*`
- `-` works too
    * Indent a level to make a nested list
        1. Ordered lists are supported.
        2. Start each item (number-period-space) like `1. `
        42. It doesn't matter what number you use, I will render them sequentially
        1. So you might want to start each line with `1.` and let me sort it out
```

Block Quote

> Angle brackets `>` are used for block quotes.
> Technically not every line needs to start with a `>` as long as there are no empty lines between paragraphs.
> Looks kinda ugly though.
>
>> Block quotes can be nested.
>>
>>> Multiple Levels
>
> Most markdown syntaxes work inside block quotes.
>
> * Lists
> * [Links](#)
> * Etc.

Here is the code:

```
> Angle brackets `>` are used for block quotes.
Technically not every line needs to start with a `>` as long as
there are no empty lines between paragraphs.
> Looks kinda ugly though.
> > Block quotes can be nested.
> > > Multiple Levels
>
> Most markdown syntaxes work inside block quotes.
>
> * Lists
> * [Links][arbitrary_id]
> * Etc.
```

Inline Code

`Inline code` is indicated by surrounding it with backticks:
`` `Inline code` ``

If your `code has ``backticks``` that need to be displayed, you can use double backticks: `` ``Code with ``backticks`` `` `` (mind the spaces preceding the final set of backticks)

Block Code

If you indent at least four spaces or one tab, I'll display a code block.

```
print('This is a code block')
print('The block must be preceded by a blank line')
print('Then indent at least 4 spaces or 1 tab')
    print('Nesting does nothing. Your code is displayed Literally')
```

I also know how to do something called [Fenced Code Blocks](#) which I will tell you about later.
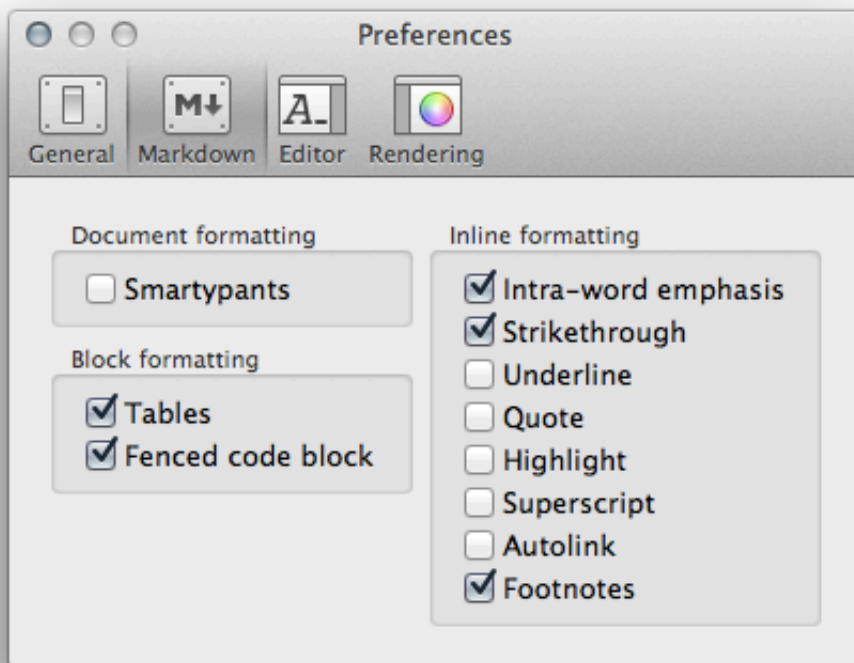

Horizontal Rules

If you type three asterisks `***` or three dashes `---` on a line, I'll display a horizontal rule:

The Markdown Preference Pane

This is where I keep all preferences related to how I parse markdown into html.

Document Formatting

The **Smartypants** extension automatically transforms straight quotes (`"` and `'`) in your text into typographer's quotes (`"` , `"` , `'` , and `'`) according to the context. Very useful if you're a typography freak like I am. Quote and Smartypants are syntactically incompatible. If both are enabled, Quote takes precedence.

Block Formatting

Table

This is a table:

First Header	Second Header
Content Cell	Content Cell
Content Cell	Content Cell

You can align cell contents with syntax like this:

Left Aligned	Center Aligned	Right Aligned
col 3 is	some wordy text	$1600
col 2 is	centered	$12
zebra stripes	are neat	$1

The left- and right-most pipes (`|`) are only aesthetic, and can be omitted. The spaces don't matter, either. Alignment depends solely on `:` marks.

Fenced Code Block

This is a fenced code block:

```
print('Hello world!')
```

You can also use waves (`~`) instead of back ticks (`` ` ``):

```
print('Hello world!')
```

You can add an optional language ID at the end of the first line. The language ID will only be used to highlight the code inside if you tick the **Enable highlighting in code blocks** option. This is what happens if

you enable it:

```
~~~python
foo = (1, 2, 3, 4)
bar = (5, 6, 7, 8)
for f, b in zip(foo, bar):
    print f, b
# Prints:
# 1 5
# 2 6
# 3 7
# 4 8
~~~
```

```
foo = (1, 2, 3, 4)
bar = (5, 6, 7, 8)
for f, b in zip(foo, bar):
    print f, b
# Prints:
# 1 5
# 2 6
# 3 7
# 4 8
```

I support many popular languages as well as some generic syntax descriptions that can be used if your language of choice is not supported. See relevant sections on the official site for a full list of supported syntaxes.

Inline Formatting

The following is a list of optional inline markups supported:

Option name	Markup	Result if enabled
Intra-word emphasis	So A*maz*ing	So A*maz*ing
Strikethrough	~~Much wow~~	~~Much wow~~
Underline [2]	_So doge_	So doge
Quote [3]	"Such editor"	"Such editor"
Highlight	==So good==	So good
Superscript	hoge^(fuga)	hoge^{fuga}
Autolink	http://t.co	http://t.co
Footnotes	[^4] and [^4]:	[4] and footnote 4

The Rendering Preference Pane

This is where I keep preferences relating to how I render and style the parsed markdown in the preview

window.
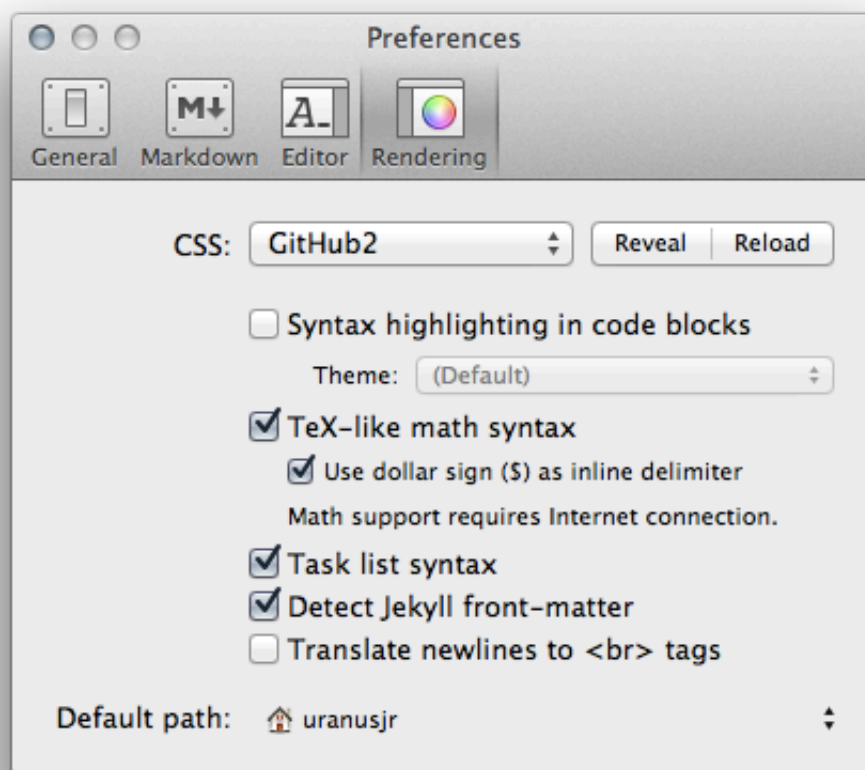

CSS

You can choose different css files for me to use to render your html. You can even customize or add your own custom css files.

Syntax Highlighting

You have already seen how I can syntax highlight your fenced code blocks. See the Fenced Code Block section if you haven't! You can also choose different themes for syntax highlighting.

TeX-like Math Syntax

I can also render TeX-like math syntaxes, if you allow me to.[5] I can do inline math like this: \(1 + 1 \) or this (in MathML): $1 + 1$, and block math:

\[A^T_S = B \]

or (in MathML)

$$A_S^T = B$$

Task List Syntax

1. [x] I can render checkbox list syntax
   - [x] I support nesting
   - [x] I support ordered *and* unordered lists

2. [ ] I don't support clicking checkboxes directly in the html window

Jekyll front-matter

If you like, I can display Jekyll front-matter in a nice table. Just make sure you put the front-matter at the very beginning of the file, and fence it with `---` . For example:

```
---
title: "Macdown is my friend"
date: 2014-06-06 20:00:00
---
```

Render newline literally

Normally I require you to put two spaces and a newline (aka return) at the end of a line in order to create a line break. If you like, I can render a newline any time you end a line with a newline. However, if you enable this, markdown that looks lovely when I render it might look pretty funky when you let some *other* program render it.

The General Preferences Pane

This is where I keep preferences related to application behavior.
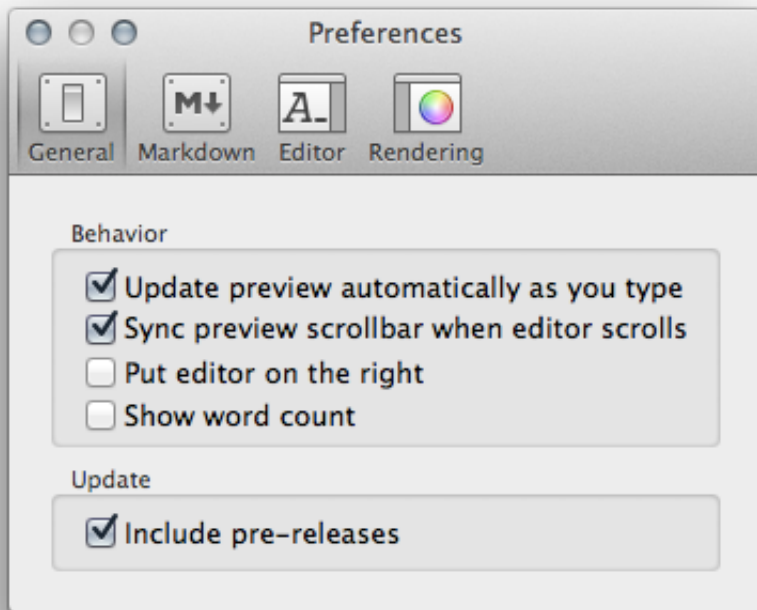

The General Preferences Pane allows you to tell me how you want me to behave. For example, do you want me to make sure there is a document open when I launch? You can also tell me if I should constantly update the preview window as you type, or wait for you to hit `command-R` instead. Maybe you prefer your editor window on the right? Or to see the word-count as you type. This is also the place to tell me if you are interested in pre-releases of me, or just want to stick to better-tested official releases.

The Editor Preference Pane

This is where I keep preferences related to the behavior and styling of the editing window.
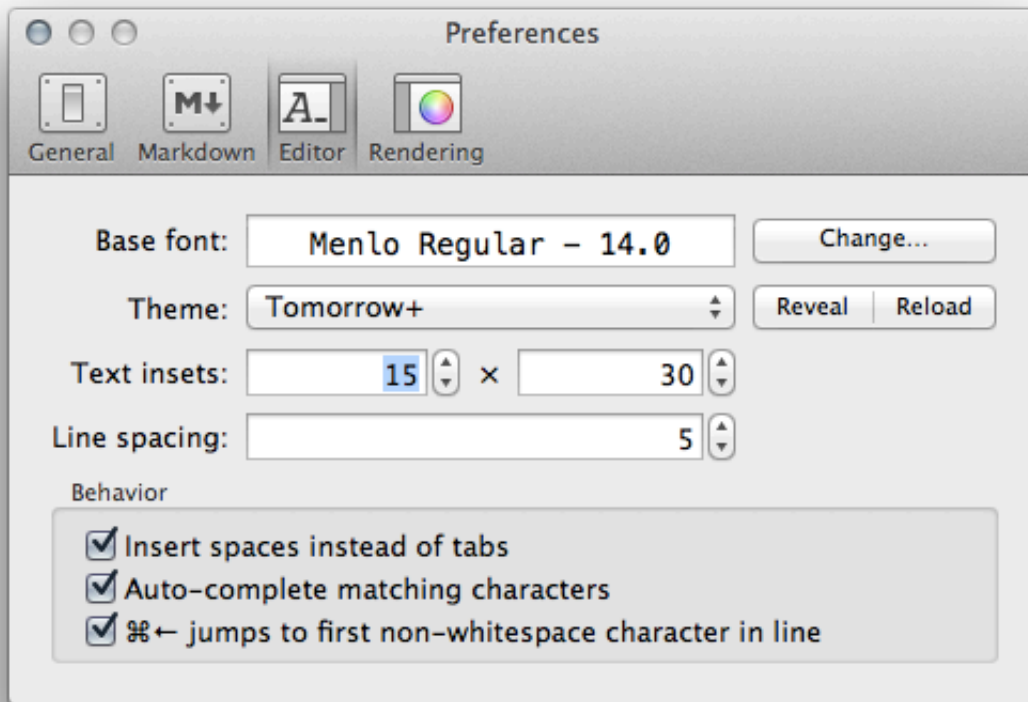

Styling

My editor provides syntax highlighting. You can edit the base font and the coloring/sizing theme. I provided some default themes (courtesy of [Mou](#)'s creator, Chen Luo) if you don't know where to start.

You can also edit, or even add new themes if you want to! Just click the **Reveal** button, and start moving things around. Remember to use the correct file extension (`.styles`), though. I'm picky about that.

I offer auto-completion and other functions to ease your editing experience. If you don't like it, however, you can turn them off.

Hack On

That's about it. Thanks for listening. I'll be quiet from now on (unless there's an update about the app—I'll remind you for that!).

Happy writing!

---

1. If **Underlines** is turned on, `_this notation_` will render as underlined instead of emphasized ↵

2. If **Underline** is disabled `_this_` will be rendered as *emphasized* instead of being underlined. ↵

3. **Quote** replaces literal `"` characters with html `<q>` tags. **Quote** and **Smartypants** are syntactically incompatible. If both are enabled, **Quote** takes precedence. Note that **Quote** is different from *blockquote*, which is part of standard Markdown. ↵

4. You don't have to use a number. Arbitrary things like `[^footy note4]` and `[^footy note4]:` will also work. But they will *render* as numbered footnotes. Also, no need to keep your footnotes in order, I will sort out the order for you so they appear in the same order they were referenced in the text body. You can even keep some footnotes near where you referenced them, and collect others at the bottom of the file in the traditional place for footnotes. ↵

5. Internet connection required. ↵
